1 Serial Communication Protocol

ADVANCED Motion Controls' serial protocol is a binary, ping/pong protocol that accesses Indexes and Offsets within the servo drive. Messages from the master and responses from the drive are both wrapped in Ethernet packets. The Ethernet protocol contains the serial protocol, using either UDP or TCP.

1.1 Physical Layer

The physical layer is the RJ45 Ethernet Standard (IEEE 802.3).

1.2 Message Structure (Command)

The master (or host) sends the following command/request frame:

FIGURE 1.1 Host Read/Write Command

Header Section						Data Section
SOF	Address	Control	Index	Offset	Length	Data (Hex) LSB first

Frames sent over TCP/IP do not need the SOF or the address - these are dropped from the frame header. The header just consists of CONTROL, INDEX, OFFSET, and LENGTH bytes for command/request frames. Frames sent over TCP/IP are frames exchanged with port 0xCCCC on the drive.

> **i** Note
>
> Note - The TCP parameters need to be adjusted so that the stream protocol doesn't break up or concatenate serial frames.

IP/UDP communication uses a revised format with the frames being sent over IP/UDP to port 4168. The first byte (which would be the SOF) is reserved and is usually zero. The second byte is the unit address which is ignored for single axis units, but is used on multi-axis units to direct

communications to the appropriate drive or slave. Multi-axis unit addressing is automatically set to 63 for the master, then 62, 61, and so on for the successive slave axes.

S.O.F. (Start Of Frame) (UDP ONLY) Start of Frame - reserved, and usually set to zero.

Address (UDP ONLY) The address field is ignored for single-axis configurations, but should still be set to 63 (3Fh) as the default.

Control Byte 8-bit control field that includes the read/write marker and a rolling frame number. The read/write marker is in bits 0 and 1, and will show 01h for a read and 02h for a write. The frame number is in the next three bits and counts up before rolling over.

Index Contains the command index number. The basic operation of *ADVANCED* Motion Controls' servo drives relies on a list of indexes that contain parameters within them (just like an array). Each index is an 8-bit number that identifies each "parameter structure." In order to change parameters in the drive, the correct parameter structure must be located and the corresponding index used in the actual message frame. Use "Command Dictionary" on page 10 to locate the appropriate index for a particular parameter.

Offset Offset of the data into the index data structure. In order to identify a parameter within a specific index, an offset value is used. This value indicates in "words" (1 word = 2 bytes) how far into the index a parameter is. If there are 3 2-word parameters in a particular index, then the total length of the index is 6 bytes. The offset of each parameter is 0, 2, and 4.

Offset values are Zero Based therefore if it is desired to access parameter 3, and an offset of 4 is used: This indicates the entry point into the parameter structure is 8 bytes down and the next 2 words correspond to parameter 3.

All parameter offsets should be provided in the Command Dictionary. If they are not, they can usually be calculated by looking at the data type of all the parameters in an index and adding up the bytes to get to the desired parameter. Divide the number of bytes by 2, which should always be an integer.

Length The number of words (2 bytes) in the DATA field, in the case of a 'write' index, or the number of words (2 bytes) to be read in the case of a 'read' index.

Data Variable length data field, containing a number of data words (as determined by LENGTH), in case of a 'write' request, or nothing in case of a 'read' request. Data is always in Little Endian format. Since the length is in half words, then there will always be an even number of bytes of data.

1.3 Message Structure (Reply)

The destination node (slave) responds with the following command frame:

FIGURE 1.2 **Node Response**

Header Section						Data Section
SOF	Address	Control	Status	RFU	Length	Data (Hex) LSB first

S.O.F. (Start Of Frame)   (UDP ONLY) Start of Frame - reserved, and usually set to zero.

Address   (UDP ONLY) Always FFh in the case of Node Response to host. All nodes will always reply with FFh.

Control Byte   8-bit control field that indicates whether data is included in the response message and a rolling frame number. The data indication will read 00h if no data is included and 02h if data is included.

Status 1   8-bit field, with following bit meanings:

TABLE 1.1 **Status Bits**

Bit	Description
0	Command complete. Set if command was completed.
1	Command incomplete. Set if command was not completed.
2	Invalid command. Set if command was invalid.
3	Frame error. Set in case of frame error.
4-7	Not used.

RFU   Reserved for future use.

Length   8-bit value that indicates the number of words (2 bytes) in the DATA field of the response message. If the CONTROL field indicates that the response message does not contain data, this field is undefined (but will probably be zero).

Data Words   Variable length data field, containing the number of words indicated by the LENGTH field if the CONTROL field indicates that the response message contains data. Data is in Little Endian format. Since the LENGTH field is in half words, then there will always be an even number of bytes of data.

2 Command Dictionary

2.1 Dictionary Table Format

The command dictionary provides one entry for each existing command. Since commands may or may not have parameters, the following convention is used for each entry:

TABLE 2.1 Command Table Example.

02.01h	Sub Index Name			
Data Type	**Data Range**	**Units**	**Accessibility**	**Stored to NVM**
Unsigned16	$0 - [2^{(15)} - 1]$	N/A	Read / Write*	No
Description:				
Detailed description of what this command does and how to use it.				
* This indicates a note about conditions.				

In the example of Table 2.1, the command index and parameter is referenced via the dot (.). 02h is the command index and .01h is the parameter. Commands without parameters will be referenced without the dot (.).

Furthermore, each entry has the following attributes:

- Data Type: This field specifies the data type of the command. Data types can be 8-bit, 16-bit, 32-bit, or string.
- Range: This field specifies the usable range of the values this command can contain.
- Units: This field specifies the units that apply to the value stored in this command. If the value contained in this command has no units, the field will contain "N/A." The appropriate physical unit is only supplied if there is a one-to-one relationship between the physical unit and the drive data type. For units which require scaling between a physical unit and the drive data type, an abbreviation for a drive unit is supplied. All drive units are described in "Appendix A" on page 183.
- Accessibility: This field specifies whether the command can be read or written to. If there is a * in this box, then the command may only be accessible in certain modes. See the Description box for more information about mode dependencies.
- Stored to NVM: This field specifies whether or not the command can be stored to Non Volatile Memory such that it is recalled on power up.
- Description: This field contains detailed information on the command and what it is used for.

2.2 Configuration Commands

Although the following commands are used predominately during drive setup and initialization, they are not restricted to use only during setup. Configuration commands can be divided into the following three categories.

- Administrative Commands: these commands are used for administrative operations such as loading or restoring parameters from non-volatile memory.
- Communication Commands: these commands determine the communication settings of the drive. They can only be set via the communication channel interface.
- Drive Commands: these commands define the drive configuration and are largely determined by the DriveWare setup and configuration software. Commands which contain general drive information are also available.

32.0Ah	Position Interpolation / Velocity Divider			
Data Type	**Data Range**	**Units**	**Accessibility**	**Stored to NVM**
Unsigned16	$0 - [2^{(16)} - 1]$	N/A	Read / Write	Yes

Description:

For Sin/Cos encoder interpolation, contains a value corresponding to the position interpolation. The number of position counts per Sin/Cos cycle is equal to 4 multiplied by the interpolation value. This only applies to position. The measured velocity is unaffected by the interpolation. For digital encoder feedback (BiSS, EnDat 2.2) contains a value corresponding to the Velocity Divider parameter. The Velocity Divider is used to scale down the feedback going to the velocity gains when very high resolution encoders are used. This prevents saturation of the velocity loop. For incremental encoder feedback, the Interpolation Value is 1.

	Sin/Cos Encoder	Digital Encoder
Value	Interpolation	Velocity Divider
0	1x	1
1	2x	2
2	4x	4
3	8x	8
4	16x	16

Unsigned16	N/A	N/A	Read / Write	Yes
Description:

32.10h	Encoder SinCos Error Window			
Data Type	**Data Range**	**Units**	**Accessibility**	**Stored to NVM**
Unsigned16	Integer16	N/A	Read / Write	Yes
Description:				
Contains a value corresponding to the Sin/Cos error window for drives that support a 1V peak-to-peak encoder. The valid range in physical units is 0 to 1. The window determines whether or not a feedback sensor error should be activated according to the health of a Sin/Cos encoder (see object 27.02h). If x is the error window entered in this object, then an error is activated when the health of the encoder is not within the range 1±x. See "Appendix A" on page 183 for information on scaling.

3Ch: Command Limiter Parameters

The command limiter limits the slope of the target command in any mode. It is broken into four components, where each component is assigned to one parameter. To remove any effects of the command limiter, maximize all limiter parameters. Some limiter parameters have units that change with the operating mode of the drive. For these parameters, refer to Table 2.2 to make the correct unit selection.

This command sets the maximum recovery count allowed before the Positive Velocity Limit event latches and must be actively reset in order to enable the bridge. Re-setting the recovery counter requires a connection to the AMC drive configuration software appropriate for this drive. For more information on event handling, see the Help file associated with the AMC drive configuration software.

45h: Interface Inputs   Interface inputs can be used in place of analog inputs for any function that can be assigned to an analog input. Examples of this include command source, feedback source, and motor temperature source. The units for interface inputs are dependent upon the function the interface input is assigned to as given in Table 2.11. For details on unit conversion see "Appendix A" on page 183.

1.Multiply physical units by the scaling factor to obtain drive units. Divide drive units by the scaling factor to obtain physical units.

The drive units used for a parameter depend upon the parameter type and size. Drive units must be rounded to the nearest integer and then converted to a hexadecimal base of the appropriate data type before they are written to the drive. When converting to a signed integer data type, use two's complement for representation of negative numbers (see Conversion Example 2). Some scaling factors involve drive dependent constants. These constants are given in Table A.2, along with details on determining their values.

TABLE A.2 Drive Dependent Conversion Constants

Constant	Value
K_B	DC Bus Voltage in volts. This value can be read from 0F.00h.
K_{DS}	Maximum dynamic index speed (in counts/s). This value can be read from CA.06h, CA.07h, CA.08h, and CA.09h.
K_I	Feedback interpolation value. Only applies to drives that support 1 V_{pp} Sin/Cos feedback. For all other drives, K_I = 1. When applicable, this value can be read from 32.08h.
K_{MS}	Maximum profiler speed (in counts/s) for an Accel/Decel command profile. This value can be read from 3C.18h for Configuration 0 and 3C.20h for Configuration 1.
K_{OV}	The hardware defined, DC bus, over-voltage limit of the drive in volts. This value can be read from D8.53h.
K_P	The maximum rated peak current of the drive in amps. For example, 20 for the DPRALTE-**020**B080. This value can be read from D8.58h.
K_S	Switching frequency of the drive in Hz. This value can be found on the drive datasheet, or can be read from D8.73h and divided by 65.536.

A.1.1 Conversion Example 1

Drive: DPPANIU-020B080
Feedback: 1000 Line Incremental Encoder

To specify a Motor Over Speed Limit (37.01h) of 10,000 RPM, first convert to the appropriate physical unit as shown below, keeping in mind that counts have a quadrature resolution (4X) over lines.

$$10,000\,\frac{\text{rev}}{\text{min}} \times \frac{1000\,\text{lines}}{1\,\text{rev}} \times \frac{4\,\text{counts}}{1\,\text{line}} \times \frac{1\,\text{min}}{60\,\text{sec}} = 666,666.7\,\frac{\text{counts}}{\text{sec}}.$$

Motor Over Speed is of data type Integer32 and uses DS1 drive units. Taking the appropriate 32-bit scaling factor from Table A.1 yields

$$666,666.7 \times \frac{2^{17}}{K_I K_S} = 666,666.7 \times \frac{2^{17}}{1 \times 20,000} = 4369066.9,$$

where K_I = 1 because we are not dealing with 1 V_{PP} Sin/Cos feedback. Rounding this to the nearest integer and converting to a hexadecimal base then results in

$$4369067_{10} = 42\text{AAAB}_{16}.$$

Now, to apply the setting, a value of 42AAABh would be written to sub-index 37.01h.

A.1.2 Conversion Example 2

To set a temperature parameter to $23°\text{F}$ first convert to the appropriate physical unit as shown below.

$$\frac{5}{9}(23 - 32) = -5 \, °\text{C}.$$

Referring to Table A.1, the appropriate scaling factor yields

$$-5 \times 2^{16} = -327680.$$

Because the resulting integer value is negative, two's complement notation will be used to represent its hexadecimal equivalent. To obtain the two's complement, the positive version of the desired number should be subtracted from 2^N, where N is the number of bits in the data type. Temperature parameters use the data type Integer32 so the calculation is as follows.

$$2^N - 327680 = 2^{32} - 327680 = 4294639616$$
$$4294639616_{10} = \text{FFFB0000}_{16}$$

The final step would be to write a value of FFFB0000h to the appropriate parameter.

A.2 Homing

ADVANCED Motion Controls' drives support a wide variety of homing routines. These routines rely on signals such as limit switch, home switch, and encoder index signals to achieve precise starting positions. Four objects define the speed, acceleration, and the particular homing method used. These objects are listed in the table below.

TABLE A.3 Homing Objects

Object Index	Description
3A.00h	Homing Speed During Search For Switch
3A.02h	Homing Speed During Search For Zero
3A.04h	Homing Method
3A.05h	Homing Acceleration

A.2.1 Homing Speeds

There are two homing speeds to take into consideration: the speed during the search for home switch, and the speed during the search for zero. Typically, the speed during the search for the home switch is set to be faster than the speed during the search for the index.

A.2.2 Homing Method

ADVANCED Motion Controls homing methods depend on the presence of up to three different system components: an index pulse, a home switch, and a limit switch. The simplest homing methods require just one or none of these components, whereas the more complex methods require two or all of these components. All homing methods have been summarized in Table A.4, along with their necessary components. There are a total of 35 possible homing methods, some of which are reserved and not currently specified.

A.2.3 Homing Acceleration

A single value is used to define the acceleration and deceleration of all moves during the homing routine.
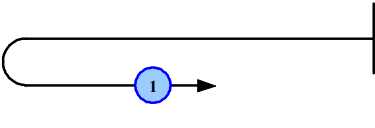

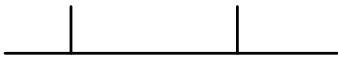

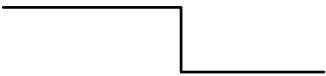

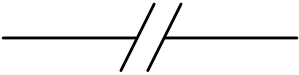

TABLE A.4   Homing Methods Summary

Homing Method	Index Pulse	Home Switch	Limit Switch
Methods 1 & 2	✓		✓
Methods 3 to 6	✓	✓	
Methods 7 to 14	✓	✓	✓
Methods 15 & 16	Reserved		
Methods 17 & 18			✓
Methods 19 to 22		✓	
Methods 23 to 30		✓	✓
Methods 31 & 32	Reserved		
Methods 33 & 34	✓		
Method 35			

Because these homing methods can become fairly complex, they are best described visually. As a result, *homing diagrams* are utilized to illustrate the behavior of each method. Homing diagrams consist of multiple components each of which is described in Figure A.1.

FIGURE A.1   Homing Diagrams

Load and physical limits	
The square near the middle of the illustration shows the load object that is to be moved. The endpoints represent physical limitations or barriers, which the load cannot travel past. The left side is in the negative direction while the right side is in the positive direction.	

Direction of travel	
The vertical line on the right side represents the starting position. The load travels in the direction of the arrow. In the illustration shown, the load begins traveling in the negative direction and then switches directions to move in the positive direction. The circle represents the home position at which point the (actual) measured position is reset to zero. The small section of arrow following the circle represents the distance traveled, past the home position, during deceleration of the load. Lastly, the number in the circle represents the number designated to that particular homing method.	
Index Pulse	
Each vertical line represents one index pulse.	
Limit/Home Switch	
A label in the actual homing diagram will be used to label a switch as either a limit/home switch. As shown, there are only two positions for a switch: high (active) or low (inactive).	
Break	
Represents a break in the diagram. This is used for representing a length of distance too large to properly scale on the diagram.	

Method 1: Homing on the Negative Limit Switch   This method uses the negative limit switch and index to home the load. If the negative limit switch is off, the motor moves in the negative direction. Once the limit switch toggles, the motor changes direction and moves until the next encoder index. Homing is complete at this point. Figure A.2 illustrates the homing diagram for this method.

FIGURE A.2 Homing on the Negative Limit Switch
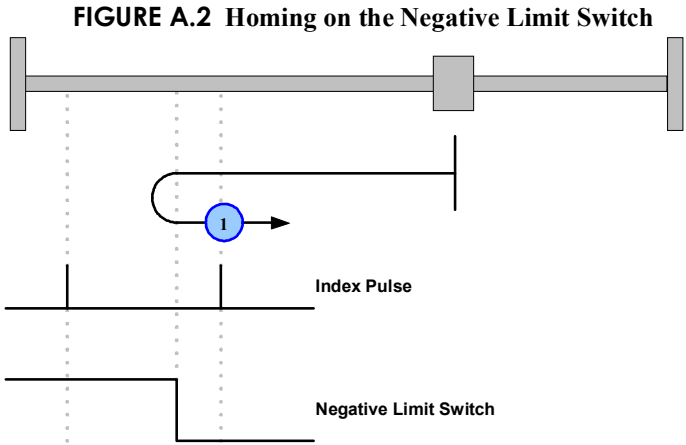

Method 2: Homing on the Positive Limit Switch
This method uses the positive limit switch and index to home the load. If the positive limit switch is off, the motor moves in the positive direction. Once the limit switch toggles, the motor changes direction and moves until the next encoder index. Homing is complete at this point. Figure A.3 illustrates the homing diagram for this method.

FIGURE A.3 **Homing on the Positive Limit Switch**
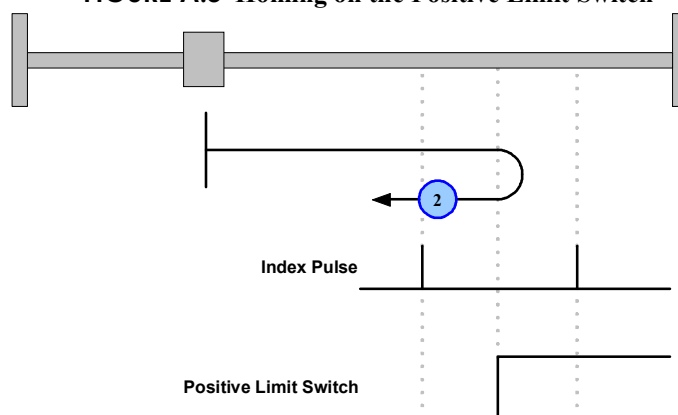

Methods 3 and 4: Homing on the Positive Home Switch
These methods use the positive home switch and index to home the load. The initial direction of movement for a given routine method is dependent on the home switch position. However, the final position is always in the same direction. Homing methods 3 and four perform the same operations, but in opposite directions with opposite home switch polarity. Figure A.4 illustrates the homing diagram for these methods.

FIGURE A.4 **Homing on the Positive Home Switch**
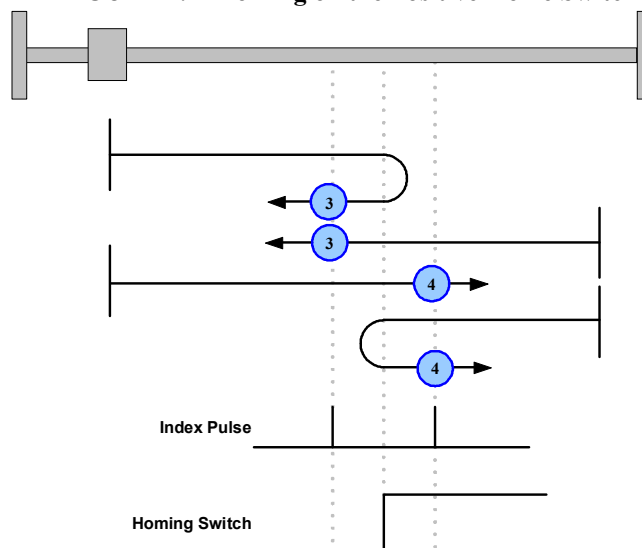

Methods 5 and 6: Homing on the Negative Home Switch
This is literally a mirror image of the homing routines used by methods 3 and 4. Figure A.5 illustrates the homing diagram for these methods.

FIGURE A.5 **Homing on the Negative Home Switch**

Index Pulse
Homing Switch

Methods 7-14: Homing on the Home Switch

These methods use all three possible homing components (index pulse, home switch, and limit switch) with the index pulse to the nearest right or left of the home switch always being the sought after home position. Methods 7 to 10 use a positive limit switch and if the starting position is outside the active home switch region the initial direction of travel is always positive. For cases where the starting position is inside the active home switch region the initial direction will depend upon the index pulse being sought after: methods 7 & 8 home towards the left home switch edge so the initial direction will be left, whereas methods 9 & 10 home towards the right home switch edge so the initial direction will be right. Note that the only difference between methods 7 & 8 is that one homes to the index pulse left of the home switch edge whereas the other homes to the index pulse to the right; the same difference holds true for methods 9 & 10. Figure A.6 illustrates the homing diagram for methods 7 to 10.

FIGURE A.6
Methods 11 to 14 use a negative limit switch instead of a positive limit switch. As a result, the initial direction will be left, instead of right, whenever the starting point is outside of the active home switch region. Outside of this difference, methods 11 to 14 are identical to methods 7 to 10. Figure A.7 illustrates the homing diagram for methods 11 to 14.

FIGURE A.7
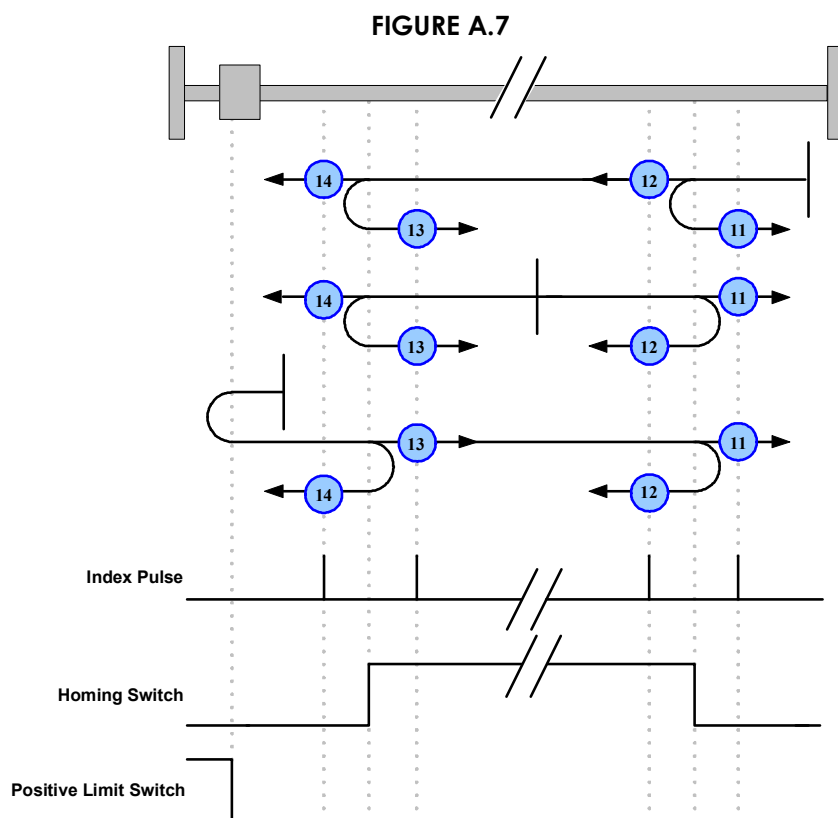

Methods 17-30: Homing without an Index Pulse:

These homing routines use the same methods as 1 to 14, except the index pulse is not used. Instead, the home position is dependant on the edge of the relevant home or limit switch. To illustrate this difference, Figure A.8 shows the homing diagram for methods 19 and 20, which are equivalent to methods 3 and 4 without the index pulse.

FIGURE A.8
Methods 33 and 34: Homing on the Index Pulse   These homing methods home to the nearest index pulse. Method 33 homes in the negative directions and method 34 homes in the positive direction.

FIGURE A.9
Method 35   This homing method requires no index pulse or switches and involves nothing more than setting the current measured position equal to the home position value, which can be accomplised in object 39.02h "Home Position Value" on page 37.

A.3 Current Limiting Algorithm

In order to understand the current limiting algorithm used by *ADVANCED* Motion Controls Digiflex Performance servo drives, it is necessary to first understand the different current limiting regions. The graph in Figure A.10 breaks the available current into three different regions.

FIGURE A.10 Current Limiting Regions
- **Continuous Region:** The commanded current is less than or equal to the continuous current limit. The available current is equal to the commanded current.
- **Peak Region:** The commanded current is between the continuous and peak current limits. The available current is equal to the commanded current for a limited time (Peak Time).
- **Foldback Region:** Commanded current is between the continuous and peak current limits of the drive. The available current is less than the commanded current. The available current decreases over time until it equals the continuous current limit. The rate of this decrease is equal to:

$$Slope = \frac{Ip - Ic}{tf}$$

Ip	Peak current limit
Ic	Continuous current limit
tf	Foldback time

A.3.1 Time-Based Peak Current Limiting

The full peak value of current is available to begin with. When a current command is equal to the peak current limit, the current begins to foldback to the continuous limit after T_p, following the same slope as given in "Current Limiting Algorithm" on page 193. Once the available current has reached the continuous current limit after t_f, the available current will be limited to the continuous current limit until the commanded current is dropped below the continuous level.

FIGURE A.11 Time-Based Peak Current Limiting
A.3.2 Time-Based Non-Peak Current Limiting

When the commanded current is between the peak and continuous current limits, the available current will begin to foldback at the intersection with the slope from "Time-Based Peak Current Limiting". The larger the commanded current, the sooner the available current will begin to foldback.

FIGURE A.12 Time-Based Non-Peak Current Limiting
A.3.3 Time-Based Current Recovery

Initially, the full peak value of current is available. A commanded current above the continuous level causes the available current to foldback to the continuous level as shown in the first graph of Figure A.13. When the commanded current drops below the continuous current limit value (A_1 in the first graph), the available current will then begin to recover along the slope of the foldback line towards the peak current level, as shown in the second graph of Figure A.13. The relationship between the commanded current and the recovered current is given as:

$$A_2 = \frac{1}{2}A_1$$

Using this relationship, you can calculate the amount of time recovered, Δt, by using the following equation:

$$\Delta t = \frac{A_1}{2(I_p - I_c)}$$

FIGURE A.13 **Time-Based Current Recovery - Foldback and Commanded Current**
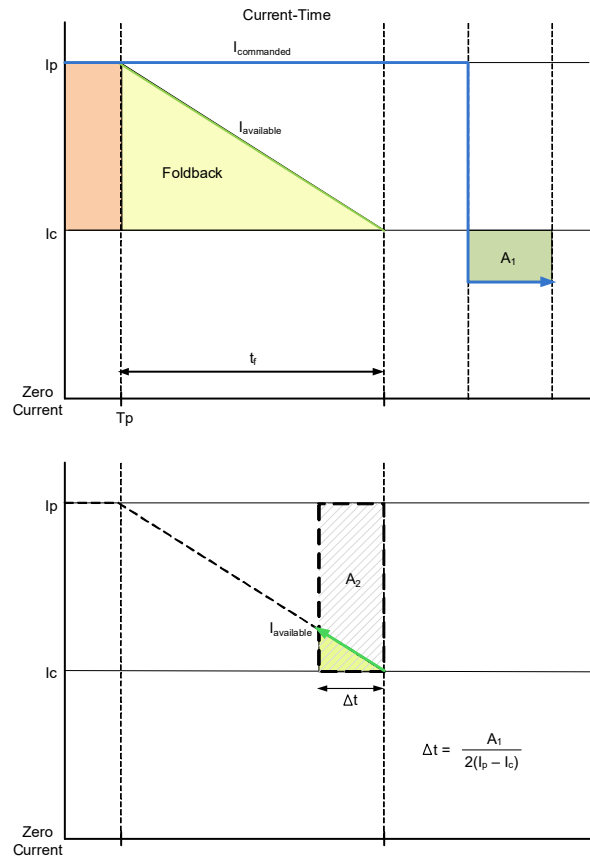

Note that it will take a command of zero current to fully recover from a full foldback condition.

A.3.4 Charge-Based Peak Current Limiting

The charge is full to begin with. When a current greater than the continuous current limit is commanded, the charge begins to decay. The loss of charge is determined by the area under the curve as shown in Figure A.14. The larger the command, the faster the charge will decay. When the charge decreases to zero, the available current will be limited to the continuous current limit until the charge is restored.

FIGURE A.14 **Charge-Based Peak Current Limiting**
A.3.5 Charge-Based Non-Peak Current Limiting

When the commanded current is between the peak and continuous current limits, the commanded current will be available for a longer period when compared to limiting at peak command. Note that the slope of the line during foldback is the same for both cases.

FIGURE A.15 Charge-Based Non-Peak Current Limiting
A.3.6 Charge-Based Current Recovery

After losing some value of charge, the charge may be recovered when the commanded value is dropped less than the continuous current limit. The amount of charge recovered depends on the magnitude of the commanded current and the amount of time in which it is commanded. The new amount of charge can be calculated by measuring the area within the curve as shown during the charge recovery phase in Figure A.16.

FIGURE A.16 Charge Recovery

ADVANCED
MOTION CONTROLS
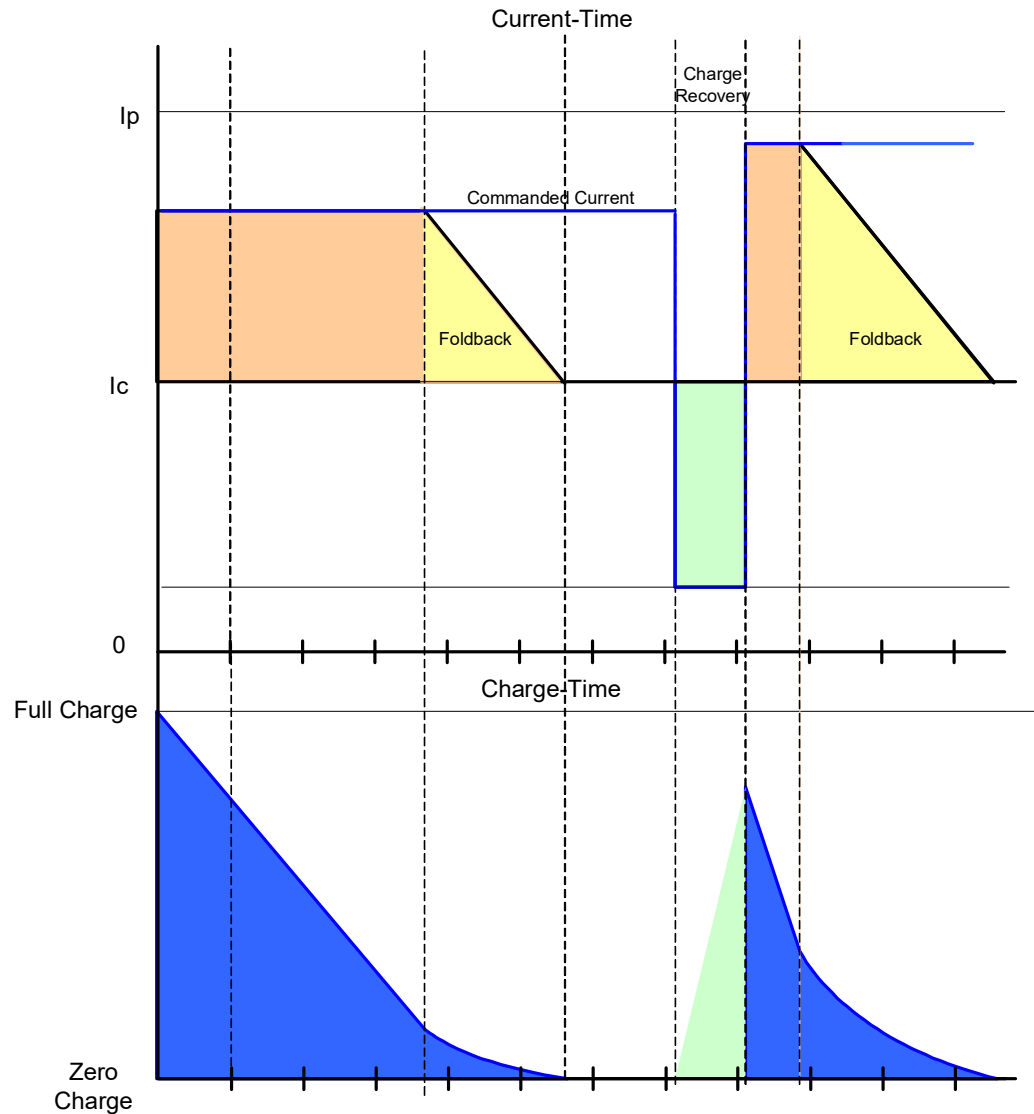

A.3.7 RMS Current Scaling

RMS Current Scaling uses the charge-based algorithm described above. The only difference is the value of the continuous current the drive is capable of outputting. The continuous RMS limit can be used when the motor is moving so that the electrical cycle frequency is greater than the upper frequency assigned to that drive. The upper frequency is typically around 5Hz or 150 RPM for a 4-pole motor. The continuous RMS value is the continuous DC value multiplied by the square root of two.

$$Icrms \equiv \sqrt{2} \cdot Icdc$$

When the electrical cycle frequency drops below the upper frequency, the continuous current drops below the RMS value. When the motor is moving at slow speeds, the continuous current is equal to the DC value of the current.
